                                <1>       ; 19/04/2013 - 14/02/2014 (Retro UNIX 8086 v1)
                                <1>       ;
                                <1>       ; 'sysexit' terminates a process. First each file that
                                <1>       ; the process has opened is closed by 'flose'. The process
                                <1>       ; status is then set to unused. The 'p.pid' table is then
                                <1>       ; searched to find children of the dying process. If any of
                                <1>       ; children are zombies (died by not waited for), they are
                                <1>       ; set free. The 'p.pid' table is then searched to find the
                                <1>       ; dying process's parent. When the parent is found, it is
                                <1>       ; checked to see if it is free or it is a zombie. If it is
                                <1>       ; one of these, the dying process just dies. If it is waiting
                                <1>       ; for a child process to die, it notified that it doesn't
                                <1>       ; have to wait anymore by setting it's status from 2 to 1
                                <1>       ; (waiting to active). It is awakened and put on runq by
                                <1>       ; 'putlu'. The dying process enters a zombie state in which
                                <1>       ; it will never be run again but stays around until a 'wait'
                                <1>       ; is completed by it's parent process. If the parent is not
                                <1>       ; found, process just dies. This means 'swap' is called with
                                <1>       ; 'u.uno=0'. What this does is the 'wswap' is not called
                                <1>       ; to write out the process and 'rswap' reads the new process
                                <1>       ; over the one that dies..i.e., the dying process is
                                <1>       ; overwritten and destroyed.
                                <1>       ;

                        <1>       ; 'syswait' waits for a process die.
                        <1>       ; It works in following way:
                        <1>       ;    1) From the parent process number, the parent's
                        <1>       ;      process name is found. The p.ppid table of parent
                        <1>       ;      names is then searched for this process name.
                        <1>       ;      If a match occurs, r2 contains child's process
                        <1>       ;      number. The child status is checked to see if it is
                        <1>       ;      a zombie, i.e; dead but not waited for (p.stat=3)
                        <1>       ;      If it is, the child process is freed and it's name
                        <1>       ;      is put in (u.r0). A return is then made via 'sysret'.
                        <1>       ;      If the child is not a zombie, nothing happens and
                        <1>       ;      the search goes on through the p.ppid table until
                        <1>       ;      all processes are checked or a zombie is found.
                        <1>       ;    2) If no zombies are found, a check is made to see if
                        <1>       ;      there are any children at all. If there are none,
                        <1>       ;      an error return is made. If there are, the parent's
                        <1>       ;      status is set to 2 (waiting for child to die),
                        <1>       ;      the parent is swapped out, and a branch to 'syswait'
                        <1>       ;      is made to wait on the next process.

;
; 'sysfork' creates a new process. This process is referred
; to as the child process. This new process core image is
; a copy of that of the caller of 'sysfork'. The only
; distinction is the return location and the fact that (u.r0)
; in the old process (parent) contains the process id (p.pid)
; of the new process (child). This id is used by 'syswait'.
; 'sysfork' works in the following manner:
;    1) The process status table (p.stat) is searched to find
;       a process number that is unused. If none are found
;       an error occurs.
;    2) when one is found, it becomes the child process number
;       and it's status (p.stat) is set to active.
;    3) If the parent had a control tty, the interrupt
;       character in that tty buffer is cleared.
;    4) The child process is put on the lowest priority run
;       queue via 'putlu'.
;    5) A new process name is gotten from 'mpid' (actually
;       it is a unique number) and is put in the child's unique
;       identifier; process id (p.pid).
;    6) The process name of the parent is then obtained and
;       placed in the unique identifier of the parent process
;       name is then put in 'u.r0'.
;    7) The child process is then written out on disk by
;       'wswap',i.e., the parent process is copied onto disk
;       and the child is born. (The child process is written
;       out on disk/drum with 'u.uno' being the child process
;       number.)
;    8) The parent process number is then restored to 'u.uno'.
;    9) The child process name is put in 'u.r0'.
;   10) The pc on the stack sp + 18 is incremented by 2 to
;       create the return address for the parent process.
;   11) The 'u.fp' list as then searched to see what files
;       the parent has opened. For each file the parent has
;       opened, the corresponding 'fsp' entry must be updated
;       to indicate that the child process also has opened
;       the file. A branch to 'sysret' is then made.

;
; Calling sequence:
;     from shell ?
; Arguments:
;     -
; Inputs: -
; Outputs: *u.r0 - child process name
; ..............................................................
;
; Retro UNIX 8086 v1 modification:
;     AX = r0 = PID (>0) (at the return of 'sysfork')
;     = process id of child a parent process returns
;     = process id of parent when a child process returns
;
;       In original UNIX v1, sysfork is called and returns as
;     in following manner: (with an example: c library, fork)
;
;     1:
;           sys   fork
;                 br 1f  / child process returns here
;           bes   2f     / parent process returns here
;           / pid of new process in r0
;           rts   pc
;     2: / parent process condionally branches here
;           mov   $-1,r0 / pid = -1 means error return
;           rts   pc
;
;     1: / child process brances here
;           clr   r0   / pid = 0 in child process
;           rts   pc
;
;     In UNIX v7x86 (386) by Robert Nordier (1999)
;           // pid = fork();
;           //
;           // pid == 0 in child process;
;           // pid == -1 means error return
;           // in child,
;           //     parents id is in par_uid if needed
;
;           _fork:
;                 mov   $.fork,eax
;                 int   $0x30
;                 jmp   1f
;                 jnc   2f
;                 jmp   cerror
;           1:
;                 mov   eax,_par_uid
;                 xor   eax,eax
;           2:
;                 ret
;
;     In Retro UNIX 8086 v1,
;     'sysfork' returns in following manner:
;
;           mov   ax, sys_fork
;           mov   bx, offset @f ; routine for child
;           int   20h
;           jc    error
;
;     ; Routine for parent process here (just after 'jc')
;           mov   word ptr [pid_of_child], ax
;           jmp   next_routine_for_parent
;
```
