3139                    <1> ;;   pages) are updated as duplicated PTE bit (AVL bit 0, PTE bit 9- is set.
3140                    <1> ;;
```

```
                                    <1> ;; !? WHAT FOR (duplication after duplication):
                                    <1> ;; In UNIX method for sys fork (a typical 'fork' application in /etc/init)
                                    <1> ;; program/executable code continues from specified location as child process,
                                    <1> ;; returns back previous code location as parent process, every child after
                                    <1> ;; every sys fork uses last image of code and data just prior the fork.
                                    <1> ;; Even if the parent code changes data, the child will not see the changed data
                                    <1> ;; after the fork. In Retro UNIX 8086 v1, parent's process segment (32KB)
                                    <1> ;; was copied to child's process segment (all of code and data) according to
                                    <1> ;; original UNIX v1 which copies all of parent process code and data -core-
                                    <1> ;; to child space -core- but swaps that core image -of child- on to disk.
                                    <1> ;; If I (Erdogan Tan) would use a method of to copy parent's core
                                    <1> ;; (complete running image of parent process) to the child process;
                                    <1> ;; for big sizes, i would force Retro UNIX 386 v1 to spend many memory pages
                                    <1> ;; and times only for a sys fork. (It would excessive reservation for sys fork,
                                    <1> ;; because sys fork usually is prior to sys exec; sys exec always establishes
                                    <1> ;; a new/fresh core -running space-, by clearing all code/data content).
                                    <1> ;; 'Read Only' page flag ensures page fault handler is needed only for a few write
                                    <1> ;; attempts between sys fork and sys exec, not more... (I say so by thinking
                                    <1> ;; of "/etc/init" content, specially.) sys exec will clear page tables and
                                    <1> ;; new/fresh pages will be used to load and run new executable/program.
                                    <1> ;; That is what for i have preferred "copy on write", "duplication" method
                                    <1> ;; for sharing same read only pages between parent and child processes.
                                    <1> ;; That is a pitty i have to use new private flag (AVL bit 0, "duplicated PTE
                                    <1> ;; belongs to child" sign) for cooperation on duplicated pages between a parent
                                    <1> ;; and it's child processes; otherwise parent process would destroy data belongs
                                    <1> ;; to its child or vice versa; or some pages would remain unclaimed
                                    <1> ;; -deallocation problem-.
                                    <1> ;; Note: to prevent conflicts, read only pages must not be swapped out...
                                    <1> ;;
                                    <1> ;; WHEN PARENT TRIES TO WRITE IT'S READ ONLY (DUPLICATED) PAGE:
                                    <1> ;; # Page fault handler will do those:
                                    <1> ;;   - 'Duplicated PTE' flag (PTE bit 9) is checked (on the failed PTE).
                                    <1> ;;   - If it is reset/clear, there is a child uses same page.
                                    <1> ;;   - Parent's read only page -previous page- is copied to a new writable page.
                                    <1> ;;   - Parent's PTE is updated as writable page, as unique page (AVL=0)
                                    <1> ;;   - (Page fault handler whill check this PTE later, if child process causes to
                                    <1> ;;     page fault due to write attempt on read only page. Of course, the previous
                                    <1> ;;     read only page will be converted to writable and unique page which belongs
                                    <1> ;;     to child process.)
                                    <1> ;; WHEN CHILD TRIES TO WRITE IT'S READ ONLY (DUPLICATED) PAGE:
                                    <1> ;; # Page fault handler will do those:
                                    <1> ;;   - 'Duplicated PTE' flag (PTE bit 9) is checked (on the failed PTE).
                                    <1> ;;   - If it is set, there is a parent uses -or was using- same page.
                                    <1> ;;   - Same PTE address within parent's page table is checked if it has same page
                                    <1> ;;     address or not.
                                    <1> ;;   - If parent's PTE has same address, child will continue with a new writable page.
                                    <1> ;;     Parent's PTE will point to same (previous) page as writable, unique (AVL=0).
                                    <1> ;;   - If parent's PTE has different address, child will continue with it's
                                    <1> ;;     own/same page but read only flag (0) will be changed to writable flag (1) and
                                    <1> ;;     'duplicated PTE (belongs to child)' flag/sign will be cleared/reset.
                                    <1> ;;
                                    <1> ;; NOTE: When a child process is terminated, read only flags of parent's page tables
                                    <1> ;;       will be set as writable (and unique) in case of child process was using
                                    <1> ;;       same pages with duplicated child PTE sign... Depending on sys fork and
                                    <1> ;;       duplication method details, it is not possible multiple child processes
                                    <1> ;;       were using same page with duplicated PTEs.
                                    <1> ;;

4476                            <1> ;;    offset value becomes it's previous offset value - 4.
4477                            <1> ;;    If the 1st page of the swap page queue is not 'accessed'
4478                            <1> ;;    the queue/list is not shifted.
4479                            <1> ;;    After the queue/list shift, newly allocated page is added
4480                            <1> ;;    to the tail of the queue at the [swpq_count*4] position.
4481                            <1> ;;    But, if [swpq_count] > 1023, the newly allocated page
4482                            <1> ;;    will not be added to the tail of swap page queue.
4483                            <1> ;;
4484                            <1> ;;    During 'swap_out' procedure, swap page queue is checked for
4485                            <1> ;;    the first non-accessed, writable page in the list,
4486                            <1> ;;    from the head to the tail. The list is shifted to left
4487                            <1> ;;    (to the head) till a non-accessed page will be found in the list.
4488                            <1> ;;    Then, this page     is swapped out (to disk) and then it is dropped
4489                            <1> ;;    from the list by a final swap queue shift. [swpq_count] value
4490                            <1> ;;    is changed. If all pages on the queue' are 'accessed',
4491                            <1> ;;    'insufficient memory' error will be returned ('swap_out'
4492                            <1> ;;    procedure will be failed)...
4493                            <1> ;;
4494                            <1> ;;    Note: If the 1st page of the queue is an 'accessed' page,
4495                            <1> ;;    'accessed' flag of the page will be reset (0) and that page
4496                            <1> ;;    (PTE) will be added to the tail of the queue after
4497                            <1> ;;    the check, if [swpq_count] < 1023. If [swpq_count] = 1024
4498                            <1> ;;    the queue will be rotated and the PTE in the head will be
4499                            <1> ;;    added to the tail after resetting 'accessed' bit.
4500                            <1> ;;
4501                            <1> ;;

<1> ;; +---------+---------+---------+---------+-- --+---------+---------+
<1> ;;
<1> ;; [swpd_next] = the first free block address in swapped page records
<1> ;;                  for next free block search by 'swap_out' procedure.
<1> ;; [swpd_size] = swap disk/file size in sectors (512 bytes)
<1> ;;           NOTE: max. possible swap disk size is 1024 GB
<1> ;;           (entire swap space must be accessed by using
<1> ;;           31 bit offset address)
<1> ;; [swpd_free] = free block (4096 bytes) count in swap disk/file space
<1> ;; [swpd_start] = absolute/start address of the swap disk/file
<1> ;;            0 for file, or beginning sector of the swap partition
<1> ;; [swp_drv] = logical drive description table addr. of swap disk/file
<1> ;;
<1> ;;
<1> ;; Method:
<1> ;;    When the memory (ram) becomes insufficient, page allocation
<1> ;;    procedure swaps out a page from memory to the swap disk
<1> ;;    (partition) or swap file to get a new free page at the memory.
<1> ;;    Swapping out is performed by using swap page queue.
<1> ;;
<1> ;;    Allocation block size of swap disk/file is equal to page size
<1> ;;    (4096 bytes). Swapping address (in sectors) is recorded
<1> ;;    into relevant page file entry as 31 bit physical (logical)
<1> ;;    offset address as 1 bit shifted to left for present flag (0).
<1> ;;    Swapped page address is between 1 and swap disk/file size - 4.
<1> ;;    Absolute physical (logical) address of the swapped page is
<1> ;;    calculated by adding offset value to the swap partition's
<1> ;;    start address. If the swap device (disk) is a virtual disk
<1> ;;    or it is a file, start address of the swap disk/volume is 0,
<1> ;;    and offset value is equal to absolute (physical or logical)
<1> ;;    address/position. (It has not to be ZERO if the swap partition
<1> ;;    is in a partitioned virtual hard disk.)
<1> ;;
<1> ;;    Note: Swap addresses are always specified/declared in sectors,
<1> ;;    not in bytes or     in blocks/zones/clusters (4096 bytes) as unit.
<1> ;;
<1> ;;    Swap disk/file allocation is mapped via 'Swap Allocation Table'
<1> ;;    at memory as similar to 'Memory Allocation Table'.
<1> ;;
<1> ;;    Every bit of Swap Allocation Table repsesents one swap block
<1> ;;    (equal to page size) respectively. Bit 0 of the S.A.T. byte 0
<1> ;;    is reserved for swap disk/file block 0 as descriptor block
<1> ;;    (also for compatibility with PTE). If bit value is ZERO,
<1> ;;    it means relevant (respective) block is in use, and,
<1> ;;    of course, if bit value is 1, it means relevant (respective)
<1> ;;      swap disk/file block is free.
<1> ;;    For example: bit 1 of the byte 128 repsesents block 1025
<1> ;;    (128*8+1) or sector (offset) 8200 on the swap disk or
<1> ;;    byte (offset/position) 4198400 in the swap file.
<1> ;;    4GB swap space is represented via 128KB Swap Allocation Table.
<1> ;;    Initial layout of Swap Allocation Table is as follows:
<1> ;;    ------------------------------------------------------------
<1> ;;    01111111111111111111111 .... 11111111111111111111111111111
<1> ;;    ------------------------------------------------------------
<1> ;;    (0 is reserved block, 1s represent free blocks respectively.)
<1> ;;    (Note: Allocation cell/unit of the table is bit, not byte)
<1> ;;
<1> ;;    ............................................................
<1> ;;
<1> ;;    'swap_out' procedure checks 'free_swap_blocks' count at first,
<1> ;;    then it searches Swap Allocation Table if free count is not
<1> ;;    zero. From begining the [swpd_next] dword value, the first bit
<1> ;;    position with value of 1 on the table is converted to swap
<1> ;;    disk/file offset address, in sectors (not 4096 bytes block).
<1> ;;    'ldrv_write' procedure is called with ldrv (logical drive
<1> ;;    number of physical swap disk or virtual swap disk)
<1> ;;    number, sector offset (not absolute sector -LBA- number),
<1> ;;    and sector count (8, 512*8 = 4096) and buffer adress
<1> ;;    (memory page). That will be a direct disk write procedure.
<1> ;;    (for preventing late memory allocation, significant waiting).
<1> ;;    If disk write procedure returns with error or free count of
<1> ;;    swap blocks is ZERO, 'swap_out' procedure will return with
<1> ;;    'insufficient memory error' (cf=1).
<1> ;;
<1> ;;    (Note: Even if free swap disk/file blocks was not zero,
<1> ;;    any disk write error will not be fixed by 'swap_out' procedure,
<1> ;;    in other words, 'swap_out' will not check the table for other
<1> ;;    free blocks after a disk write error. It will return to
<1> ;;    the caller with error (CF=1) which means swapping is failed.
<1> ;;
<1> ;;    After writing the page on to swap disk/file address/sector,
<1> ;;    'swap_out' procesure returns with that swap (offset) sector
<1> ;;    address (cf=0).
<1> ;;
<1> ;;    ............................................................
<1> ;;
<1> ;;    'swap_in' procedure loads addressed (relevant) swap disk or
<1> ;;    file sectors at specified memory page. Then page allocation
<1> ;;    procedure updates relevant page table entry with 'present'
<1> ;;    attribute. If swap disk or file reading fails there is nothing
<1> ;;    to do, except to terminate the process which is the owner of
<1> ;;    the swapped page.
<1> ;;
<1> ;;    'swap_in' procedure sets the relevant/respective bit value
<1> ;;    in the Swap Allocation Table (as free block). 'swap_in' also
<1> ;;    updates [swpd_first] pointer if it is required.
<1> ;;
<1> ;;    ............................................................
<1> ;;
<1> ;;    Note: If [swap_enabled] value is ZERO, that means there is not
<1> ;;    a swap disk or swap file in use... 'swap_in' and 'swap_out'
<1> ;;    procedures ans 'swap page que' procedures will not be active...
<1> ;;    'Insufficient memory' error will be returned by 'swap_out'
```

```
                        <1> ;;    and 'general protection fault' will be returned by 'swap_in'
                        <1> ;;    procedure, if it is called mistakenly (a wrong value in a PTE).
                        <1> ;;
