                                <1>       ;
                                <1>       ; 'sysexit' terminates a process. First each file that
                                <1>       ; the process has opened is closed by 'flose'. The process
                                <1>       ; status is then set to unused. The 'p.pid' table is then
                                <1>       ; searched to find children of the dying process. If any of
                                <1>       ; children are zombies (died by not waited for), they are
                                <1>       ; set free. The 'p.pid' table is then searched to find the
                                <1>       ; dying process's parent. When the parent is found, it is
```

```
                        <1>       ; checked to see if it is free or it is a zombie. If it is
                        <1>       ; one of these, the dying process just dies. If it is waiting
                        <1>       ; for a child process to die, it notified that it doesn't
                        <1>       ; have to wait anymore by setting it's status from 2 to 1
                        <1>       ; (waiting to active). It is awakened and put on runq by
                        <1>       ; 'putlu'. The dying process enters a zombie state in which
                        <1>       ; it will never be run again but stays around until a 'wait'
                        <1>       ; is completed by it's parent process. If the parent is not
                        <1>       ; found, process just dies. This means 'swap' is called with
                        <1>       ; 'u.uno=0'. What this does is the 'wswap' is not called
                        <1>       ; to write out the process and 'rswap' reads the new process
                        <1>       ; over the one that dies..i.e., the dying process is
                        <1>       ; overwritten and destroyed.
                        <1>       ;
                        <1>       ; Calling sequence:
                        <1>       ;     sysexit or conditional branch.

                            <1>       ; 'sysfork' creates a new process. This process is referred
                            <1>       ; to as the child process. This new process core image is
                            <1>       ; a copy of that of the caller of 'sysfork'. The only
                            <1>       ; distinction is the return location and the fact that (u.r0)
                            <1>       ; in the old process (parent) contains the process id (p.pid)
                            <1>       ; of the new process (child). This id is used by 'syswait'.
                            <1>       ; 'sysfork' works in the following manner:
                            <1>       ;    1) The process status table (p.stat) is searched to find
                            <1>       ;      a process number that is unused. If none are found
                            <1>       ;      an error occurs.
                            <1>       ;    2) when one is found, it becomes the child process number
                            <1>       ;      and it's status (p.stat) is set to active.
                            <1>       ;    3) If the parent had a control tty, the interrupt
                            <1>       ;      character in that tty buffer is cleared.
                            <1>       ;    4) The child process is put on the lowest priority run
                            <1>       ;      queue via 'putlu'.
```

```
1010                                    <1>       ;    5) A new process name is gotten from 'mpid' (actually
1011                                    <1>       ;      it is a unique number) and is put in the child's unique
1012                                    <1>       ;      identifier; process id (p.pid).
1013                                    <1>       ;    6) The process name of the parent is then obtained and
1014                                    <1>       ;      placed in the unique identifier of the parent process
1015                                    <1>       ;      name is then put in 'u.r0'.
1016                                    <1>       ;    7) The child process is then written out on disk by
1017                                    <1>       ;      'wswap',i.e., the parent process is copied onto disk
1018                                    <1>       ;      and the child is born. (The child process is written
1019                                    <1>       ;      out on disk/drum with 'u.uno' being the child process
1020                                    <1>       ;      number.)
1021                                    <1>       ;    8) The parent process number is then restored to 'u.uno'.
1022                                    <1>       ;    9) The child process name is put in 'u.r0'.
1023                                    <1>       ;   10) The pc on the stack sp + 18 is incremented by 2 to
1024                                    <1>       ;      create the return address for the parent process.
1025                                    <1>       ;   11) The 'u.fp' list as then searched to see what files
1026                                    <1>       ;      the parent has opened. For each file the parent has
1027                                    <1>       ;      opened, the corresponding 'fsp' entry must be updated
1028                                    <1>       ;      to indicate that the child process also has opened
1029                                    <1>       ;      the file. A branch to 'sysret' is then made.
