                                <1>       ; one of these, the dying process just dies. If it is waiting
                                <1>       ; for a child process to die, it notified that it doesn't
                                <1>       ; have to wait anymore by setting it's status from 2 to 1
                                <1>       ; (waiting to active). It is awakened and put on runq by
                                <1>       ; 'putlu'. The dying process enters a zombie state in which
                                <1>       ; it will never be run again but stays around until a 'wait'
                                <1>       ; is completed by it's parent process. If the parent is not
                                <1>       ; found, process just dies. This means 'swap' is called with
                                <1>       ; 'u.uno=0'. What this does is the 'wswap' is not called
                                <1>       ; to write out the process and 'rswap' reads the new process
                                <1>       ; over the one that dies..i.e., the dying process is
                                <1>       ; overwritten and destroyed.
                                <1>       ;
                                <1>       ; Calling sequence:
                                <1>       ;     sysexit or conditional branch.
                                <1>       ; Arguments:

```
4105                                <1>       ; 'sysfork' creates a new process. This process is referred
4106                                <1>       ; to as the child process. This new process core image is
4107                                <1>       ; a copy of that of the caller of 'sysfork'. The only
4108                                <1>       ; distinction is the return location and the fact that (u.r0)
4109                                <1>       ; in the old process (parent) contains the process id (p.pid)
4110                                <1>       ; of the new process (child). This id is used by 'syswait'.
4111                                <1>       ; 'sysfork' works in the following manner:
4112                                <1>       ;    1) The process status table (p.stat) is searched to find
4113                                <1>       ;       a process number that is unused. If none are found
4114                                <1>       ;       an error occurs.
4115                                <1>       ;    2) when one is found, it becomes the child process number
4116                                <1>       ;       and it's status (p.stat) is set to active.
4117                                <1>       ;    3) If the parent had a control tty, the interrupt
4118                                <1>       ;       character in that tty buffer is cleared.
4119                                <1>       ;    4) The child process is put on the lowest priority run
4120                                <1>       ;       queue via 'putlu'.
4121                                <1>       ;    5) A new process name is gotten from 'mpid' (actually
4122                                <1>       ;       it is a unique number) and is put in the child's unique
4123                                <1>       ;       identifier; process id (p.pid).
4124                                <1>       ;    6) The process name of the parent is then obtained and
4125                                <1>       ;       placed in the unique identifier of the parent process
4126                                <1>       ;       name is then put in 'u.r0'.
4127                                <1>       ;    7) The child process is then written out on disk by
4128                                <1>       ;       'wswap',i.e., the parent process is copied onto disk
4129                                <1>       ;       and the child is born. (The child process is written
4130                                <1>       ;       out on disk/drum with 'u.uno' being the child process
4131                                <1>       ;       number.)
4132                                <1>       ;    8) The parent process number is then restored to 'u.uno'.
4133                                <1>       ;    9) The child process name is put in 'u.r0'.
4134                                <1>       ;   10) The pc on the stack sp + 18 is incremented by 2 to
4135                                <1>       ;       create the return address for the parent process.
4136                                <1>       ;   11) The 'u.fp' list as then searched to see what files
4137                                <1>       ;       the parent has opened. For each file the parent has
4138                                <1>       ;       opened, the corresponding 'fsp' entry must be updated
4139                                <1>       ;       to indicate that the child process also has opened
4140                                <1>       ;       the file. A branch to 'sysret' is then made.
4141                                <1>       ;
4142                                <1>       ; Calling sequence:
4143                                <1>       ;       from shell ?
4144                                <1>       ; Arguments:
